AROMATIC SULFONE HYDROXAMATES AND THEIR USE AS PROTEASE INHIBITORS

PRIORITY CLAIM TO RELATED PATENT APPLICATION

5 [1] This patent claims priority to U.S. Provisional Patent Application Serial No. 60/290,375 (filed May 11, 2001). The entire text of U.S. Provisional Patent Application Serial No. 60/290,375 is incorporated by reference into this patent.

FIELD OF THE INVENTION

10 [2] This invention is directed generally to proteinase (also known as “protease”) inhibitors, and, more particularly, to aromatic sulfone hydroxamates (also known as “aromatic sulfone hydroxamic acids”) that, *inter alia*, inhibit matrix metalloproteinase (also known as “matrix metalloprotease” or “MMP”) activity and/or aggrecanase activity. This invention also is directed to compositions of such inhibitors,
15 intermediates for the syntheses of such inhibitors, methods for making such inhibitors, and methods for preventing or treating conditions associated with MMP activity and/or aggrecanase activity, particularly pathological conditions.

BACKGROUND OF THE INVENTION

20 [3] Connective tissue is a required component of all mammals. It provides rigidity, differentiation, attachments, and, in some cases, elasticity. Connective tissue components include, for example, collagen, elastin, proteoglycans, fibronectin, and laminin. These biochemicals make up (or are components of) structures, such as skin, bone, teeth, tendon, cartilage, basement membrane, blood vessels, cornea, and vitreous
25 humor.

 [4] Under normal conditions, connective tissue turnover and/or repair processes are in equilibrium with connective tissue production. Degradation of connective tissue is carried out by the action of proteinases released from resident tissue cells and/or invading inflammatory or tumor cells.

30 [5] Matrix metalloproteinases, a family of zinc-dependent proteinases, make up a major class of enzymes involved in degrading connective tissue. Matrix metalloproteinases are divided into classes, with some members having several different

names in common use. Examples are: MMP-1 (also known as collagenase 1, fibroblast collagenase, or EC 3.4.24.3); MMP-2 (also known as gelatinase A, 72kDa gelatinase, basement membrane collagenase, or EC 3.4.24.24), MMP-3 (also known as stromelysin 1 or EC 3.4.24.17), proteoglycanase, MMP-7 (also known as matrilysin), MMP-8 (also known as collagenase II, neutrophil collagenase, or EC 3.4.24.34), MMP-9 (also known as gelatinase B, 92kDa gelatinase, or EC 3.4.24.35), MMP-10 (also known as stromelysin 2 or EC 3.4.24.22), MMP-11 (also known as stromelysin 3), MMP-12 (also known as metalloelastase, human macrophage elastase or HME), MMP-13 (also known as collagenase 111), and MMP-14 (also known as MT1-MMP or membrane MMP). *See, generally, Woessner, J.F., "The Matrix Metalloprotease Family" in Matrix Metalloproteinases, pp.1-14 (Edited by Parks, W.C. & Mecham, R.P., Academic Press, San Diego, CA 1998).*

[6] Excessive breakdown of connective tissue by MMPs is a feature of many pathological conditions. Inhibition of MMPs therefore provides a control mechanism for tissue decomposition to prevent and/or treat these pathological conditions. Such pathological conditions generally include, for example, tissue destruction, fibrotic diseases, pathological matrix weakening, defective injury repair, cardiovascular diseases, pulmonary diseases, kidney diseases, liver diseases, ophthalmologic diseases, and diseases of the central nervous system. Specific examples of such conditions include, for example, rheumatoid arthritis, osteoarthritis, septic arthritis, multiple sclerosis, a decubitus ulcer, corneal ulceration, epidermal ulceration, gastric ulceration, tumor metastasis, tumor invasion, tumor angiogenesis, periodontal disease, liver cirrhosis, fibrotic lung disease, emphysema, otosclerosis, atherosclerosis, proteinuria, coronary thrombosis, dilated cardiomyopathy, congestive heart failure, aortic aneurysm, epidermolysis bullosa, bone disease, Alzheimer's disease, defective injury repair (*e.g.*, weak repairs, adhesions such as post-surgical adhesions, and scarring), post-myocardial infarction, bone disease, and chronic obstructive pulmonary disease.

[7] Matrix metalloproteinases also are involved in the biosynthesis of tumor necrosis factors (TNFs). Tumor necrosis factors are implicated in many pathological conditions. TNF- α , for example, is a cytokine that is presently thought to be produced initially as a 28 kD cell-associated molecule. It is released as an active, 17 kD form that can mediate a large number of deleterious effects *in vitro* and *in vivo*. TNF- α can cause

and/or contribute to the effects of inflammation (*e.g.*, rheumatoid arthritis), autoimmune disease, graft rejection, multiple sclerosis, fibrotic diseases, cancer, infectious diseases (*e.g.*, malaria, mycobacterial infection, meningitis, etc.), fever, psoriasis, cardiovascular diseases (*e.g.*, post-ischemic reperfusion injury and congestive heart failure), pulmonary diseases, hemorrhage, coagulation, hyperoxic alveolar injury, radiation damage, and acute phase responses like those seen with infections and sepsis and during shock (*e.g.*, septic shock and hemodynamic shock). Chronic release of active TNF- α can cause cachexia and anorexia. TNF- α also can be lethal.

[8] Inhibiting TNF (and related compounds) production and action is an important clinical disease treatment. Matrix metalloproteinase inhibition is one mechanism that can be used. MMP (*e.g.*, collagenase, stromelysin, and gelatinase) inhibitors, for example, have been reported to inhibit TNF- α release. *See, e.g.*, Gearing et al. *Nature* 376, 555-557 (1994). *See also*, McGeehan et al. *See also*, *Nature* 376, 558-561 (1994). MMP inhibitors also have been reported to inhibit TNF- α convertase, a metalloproteinase involved in forming active TNF- α . *See, e.g.*, WIPO Int'l Pub. No. WO 94/24140. *See also*, WIPO Int'l Pub. No. WO 94/02466. *See also*, WIPO Int'l Pub. No. WO 97/20824.

[9] Matrix metalloproteinases also are involved in other biochemical processes in mammals. These include control of ovulation, post-partum uterine involution, possibly implantation, cleavage of APP (β -amyloid precursor protein) to the amyloid plaque, and inactivation of (α_1 -protease inhibitor (α_1 -PI). Inhibiting MMPs therefore may be a mechanism that may be used to control of fertility. In addition, increasing and maintaining the levels of an endogenous or administered serine protease inhibitor (*e.g.*, α_1 -PI) supports the treatment and prevention of pathological conditions such as emphysema, pulmonary diseases, inflammatory diseases, and diseases of aging (*e.g.*, loss of skin or organ stretch and resiliency).

[10] Numerous metalloproteinase inhibitors are known. *See, generally*, Brown, P.D., "Synthetic Inhibitors of Matrix Metalloproteinases," in *Matrix Metalloproteinases*, pp. 243-61 (Edited by Parks, W.C. & Mechem, R.P., Academic Press, San Diego, CA 1998).

[11] Metalloproteinase inhibitors include, for example, natural biochemicals, such as tissue inhibitor of metalloproteinase (TIMP), α 2-macroglobulin, and their analogs and derivatives. These are high-molecular-weight protein molecules that form inactive complexes with metalloproteinases.

5 [12] A number of smaller peptide-like compounds also have been reported to inhibit metalloproteinases. Mercaptoamide peptidyl derivatives, for example, have been reported to inhibit angiotensin converting enzyme (also known as ACE) *in vitro* and *in vivo*. ACE aids in the production of angiotensin II, a potent pressor substance in mammals. Inhibiting ACE leads to lowering of blood pressure.

10 [13] A wide variety of thiol compounds have been reported to inhibit MMPs. *See, e.g.*, W095/12389. *See also*, W096/11209. *See also*, U.S. Patent No. 4,595,700. *See also*, U.S. Patent No. 6,013,649.

[14] A wide variety of hydroxamate compounds also have been reported to inhibit MMPs. Such compounds reportedly include hydroxamates having a carbon
15 backbone. *See, e.g.*, WIPO Int'l Pub. No. WO 95/29892. *See also*, WIPO Int'l Pub. No. WO 97/24117. *See also*, WIPO Int'l Pub. No. WO 97/49679. *See also*, European Patent No. EP 0 780 386. Such compounds also reportedly include hydroxamates having peptidyl backbones or peptidomimetic backbones. *See, e.g.*, WIPO Int'l Pub. No. WO 90/05719. *See also*, WIPO Int'l Pub. No. WO 93/20047. *See also*, WIPO Int'l Pub. No.
20 WO 95/09841. *See also*, WIPO Int'l Pub. No. WO 96/06074. *See also*, Schwartz et al., *Progr. Med. Chem.*, 29:271-334(1992). *See also*, Rasmussen et al., *Pharmacol Ther.*, 75(1): 69-75 (1997). *See also*, Denis et al., *Invest New Drugs*, 15(3): 175-185 (1997). Various piperazinylsulfonylmethyl hydroxamates and piperidinylsulfonylmethyl hydroxamates have additionally been reported to inhibit MMPs. *See*, WIPO Int'l Pub. No.
25 WO 00/46221. And various aromatic sulfone hydroxamates have been reported to inhibit MMPs. *See*, WIPO Int'l Pub. No. WO 99/25687. *See also*, WIPO Int'l Pub. No. WO 00/50396. *See also*, WIPO Int'l Pub. No. WO 00/69821.

[15] It is often advantageous for an MMP inhibitor drug to target a certain MMP(s) over another MMP(s). For example, it is typically preferred to inhibit MMP-2,
30 MMP-3, MMP-9, and/or MMP-13 (particularly MMP-13) when treating and/or preventing cancer, inhibiting of metastasis, and inhibiting angiogenesis. It also is typically preferred to inhibit MMP-13 when preventing and/or treating osteoarthritis. *See, e.g.*, Mitchell et

al., *J Clin. Invest.*, 97:761-768 (1996). *See also*, Reboul et al., *J Clin. Invest.*, 97:2011-2019 (1996). Normally, however, it is preferred to use a drug that has little or no inhibitory effect on MMP-1 and MMP-14. This preference stems from the fact that both MMP-1 and MMP-14 are involved in several homeostatic processes, and inhibition of
5 MMP-1 and/or MMP-14 consequently tends to interfere with such processes.

[16] Many known MMP inhibitors exhibit the same or similar inhibitory effects against each of the MMPs. For example, batimastat (a peptidomimetic hydroxamate) has been reported to exhibit IC_{50} values of from about 1 to about 20 nM against each of MMP-1, MMP-2, MMP-3, MMP-7, and MMP-9. Marimastat (another peptidomimetic
10 hydroxamate) has been reported to be another broad-spectrum MMP inhibitor with an enzyme inhibitory spectrum similar to batimastat, except that Marimastat reportedly exhibited an IC_{50} value against MMP-3 of 230 nM. *See* Rasmussen et al., *Pharmacol. Ther.*, 75(1): 69-75 (1997).

[17] Meta analysis of data from Phase I/II studies using Marimastat in patients
15 with advanced, rapidly progressive, treatment-refractory solid tumor cancers (colorectal, pancreatic, ovarian, and prostate) indicated a dose-related reduction in the rise of cancer-specific antigens used as surrogate markers for biological activity. Although Marimastat exhibited some measure of efficacy via these markers, toxic side effects reportedly were observed. The most common drug-related toxicity of Marimastat in those
20 clinical trials was musculoskeletal pain and stiffness, often commencing in the small joints in the hands, and then spreading to the arms and shoulder. A short dosing holiday of 1-3 weeks followed by dosage reduction reportedly permits treatment to continue. *See* Rasmussen et al., *Pharmacol. Ther.*, 75(1): 69-75 (1997). It is thought that the lack of specificity of inhibitory effect among the MMPs may be the cause of that effect.

[18] Another enzyme implicated in pathological conditions associated with
25 excessive degradation of connective tissue is aggrecanase, particularly aggrecanase-1 (also known as ADAMTS-4). Specifically, articular cartilage contains large amounts of the proteoglycan aggrecan. Proteoglycan aggrecan provides mechanical properties that help articular cartilage in withstanding compressive deformation during joint articulation. The
30 loss of aggrecan fragments and their release into synovial fluid caused by proteolytic cleavages is a central pathophysiological event in osteoarthritis and rheumatoid arthritis. It has been reported that two major cleavage sites exist in the proteolytically sensitive

interglobular domains at the N-terminal region of the aggrecan core protein. One of those sites has been reported to be cleaved by several matrix metalloproteases. The other site, however, has been reported to be cleaved by aggrecanase-1. Thus, inhibiting excessive aggrecanase activity provides an additional and/or alternative prevention or treatment method for inflammatory conditions. *See generally*, Tang, B. L., "ADAMTS: A Novel Family of Extracellular Matrix Proteases," *Int'l Journal of Biochemistry & Cell Biology*, 33, pp. 33-44 (2001). Such diseases reportedly include, for example, osteoarthritis, rheumatoid arthritis, joint injury, reactive arthritis, acute pyrophosphate arthritis, and psoriatic arthritis. *See, e.g.*, European Patent Application Publ. No. EP 1 081 137 A1.

10 [19] In addition to inflammatory conditions, there also is evidence that inhibiting aggrecanase may be used for preventing or treating cancer. For example, excessive levels of aggrecanase-1 reportedly have been observed with a ghoma cell line. It also has been postulated that the enzymatic nature of aggrecanase and its similarities with the MMPs would support tumor invasion, metastasis, and angiogenesis. *See* Tang, *Int'l Journal of Biochemistry & Cell Biology*, 33, pp. 33-44 (2001).

15 [20] Various hydroxamate compounds have been reported to inhibit aggrecanase-1. Such compounds include, for example, those described in European Patent Application Publ. No. EP 1 081 137 A1. Such compounds also include, for example, those described in WIPO PCT Int'l Publ. No. WO 00/09000. Such compounds further include, for example, those described in WIPO PCT Int'l Publ. No. WO 00/59874.

20 [21] In view of the importance of hydroxamate compounds in the prevention or treatment of several pathological conditions and the lack of enzyme specificity exhibited by two of the more potent MMP-inhibitor drugs that have been in clinical trials, there continues to be a need for hydroxamates having greater enzyme specificity (preferably toward MMP-2, MMP-9, MMP-13, and/or aggrecanase (particularly toward MMP-13 in some instances, toward both MMP-2 and MMP-9 in other instances, and aggrecanase in yet other instances), while exhibiting little or no inhibition of MMP-1 and/or MMP-14. The following disclosure describes hydroxamate compounds that tend to exhibit such desirable activities.

30

SUMMARY OF THE INVENTION

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[54] This detailed description of preferred embodiments is intended only to acquaint others skilled in the art with Applicants' invention, its principles, and its practical application so that others skilled in the art may adapt and apply the invention in its numerous forms, as they may be best suited to the requirements of a particular use. This detailed description and its specific examples, while indicating preferred embodiments of this invention, are intended for purposes of illustration only. This invention, therefore, is not limited to the preferred embodiments described in this patent, and may be variously modified.

A. Compounds of This Invention

[55] In accordance with this invention, it has been found that certain aromatic sulfone hydroxamates tend to be effective for inhibiting MMPs, particularly those associated with excessive (or otherwise pathological) breakdown of connective tissue.

Specifically, Applicants have found that these hydroxamates tend to be effective for inhibiting proteases (particularly MMP-2, MMP-9, MMP-13, other MMP's associated with pathological conditions, and/or aggrecanase) that are often particularly destructive to tissue if present or generated in abnormally excessive quantities or concentrations. Moreover, Applicants have discovered that these hydroxamates tend to be selective toward inhibiting pathological protease activity, while avoiding excessive inhibition of other proteases (particularly MMP-1 and/or MMP-14) that are typically essential to normal bodily function (*e.g.*, tissue turnover and repair).

B. Salts of the Compounds of this Invention

[708] The compounds of this invention can be used in the form of salts derived from inorganic or organic acids. Depending on the particular compound, a salt of the compound may be advantageous due to one or more of the salt's physical properties, such as enhanced pharmaceutical stability in differing temperatures and humidities, or a

desirable solubility in water or oil. In some instances, a salt of a compound also may be used as an aid in the isolation, purification, and/or resolution of the compound.

[709] Where a salt is intended to be administered to a patient (as opposed to, for example, being used in an *in vitro* context), the salt preferably is pharmaceutically acceptable. Pharmaceutically acceptable salts include salts commonly used to form alkali metal salts and to form addition salts of free acids or free bases. In general, these salts typically may be prepared by conventional means with a compound of this invention by reacting, for example, the appropriate acid or base with the compound.

[710] Pharmaceutically-acceptable acid addition salts of the compounds of this invention may be prepared from an inorganic or organic acid. Examples of suitable inorganic acids include hydrochloric, hydrobromic acid, hydroiodic, nitric, carbonic, sulfuric, and phosphoric acid. Suitable organic acids generally include, for example, aliphatic, cycloaliphatic, aromatic, araliphatic, heterocyclyl, carboxylic, and sulfonic classes of organic acids. Specific examples of suitable organic acids include acetate, trifluoroacetate, formate, propionate, succinate, glycolate, gluconate, digluconate, lactate, malate, tartaric acid, citrate, ascorbate, glucuronate, maleate, fumarate, pyruvate, aspartate, glutamate, benzoate, anthranilic acid, mesylate, stearate, salicylate, p-hydroxybenzoate, phenylacetate, mandelate, embonate (pamoate), methanesulfonate, ethanesulfonate, benzenesulfonate, pantothenate, toluenesulfonate, 2-hydroxyethanesulfonate, sufanilate, cyclohexylaminosulfonate, algenic acid, b-hydroxybutyric acid, galactarate, galacturonate, adipate, alginate, bisulfate, butyrate, camphorate, camphorsulfonate, cyclopentanepropionate, dodecylsulfate, glycoheptanoate, glycerophosphate, hemisulfate, heptanoate, hexanoate, nicotinate, 2-naphthalesulfonate, oxalate, palmoate, pectinate, persulfate, 3-phenylpropionate, picrate, pivalate, thiocyanate, tosylate, and undecanoate.

Preferred metallic salts include alkali metal (group Ia) salts, alkaline earth metal (group IIa) salts, and other physiological acceptable metal salts. Such salts may be made from aluminum, calcium, lithium, magnesium, potassium, sodium, and zinc. Preferred organic salts can be made from tertiary amines and quaternary amine salts, such as tromethamine, diethylamine, N,N'-dibenzylethylenediamine, chlorprocaine, choline, diethanolamine, ethylenediamine, meglumine (N-methylglucamine), and procaine. Basic nitrogen-containing groups can be

The target MMP is/are typically MMP-2, MMP-9, and/or MMP-13, with MMP-13 often being a particularly preferred target. The preferred total daily dose of the hydroxamate or salt thereof (administered in single or divided doses) is typically from about 0.001 to about 100 mg/kg, more preferably from about 0.001 to about 30 mg/kg, and even more preferably from about 0.01 to about 10 mg/kg (*i.e.*, mg hydroxamate or salt thereof per kg body weight). 15 [744] In some instances, the number of carbon atoms in a hydrocarbyl (*e.g.*, alkyl, alkenyl, alkynyl, or cycloalkyl) is indicated by the prefix "C_x-C_y-", wherein x is the minimum and y is the maximum number of carbon atoms in the substituent. Thus, for example, "C₁-C₆-alkyl" refers to an alkyl containing from 1 to 6 carbon atoms. Illustrating further, C₃-C₆-cycloalkyl means a saturated hydrocarbyl ring containing from 3 to 6
20 carbon ring atoms.

The term “monosubstituted amino” (alone or in combination with another term(s)) means an amino wherein one of the hydrogen radicals is replaced by a non-hydrogen substituent. The term “disubstituted amino” (alone or in combination with another

[753] If a substituent is described as being “substituted”, a non-hydrogen radical is in the place of a hydrogen radical on a carbon or nitrogen of the substituent. Thus, for example, a substituted alkyl substituent is an alkyl substituent wherein at least one non-
20 hydrogen radical is in the place of a hydrogen radical on the alkyl substituent. To illustrate, monofluoroalkyl is alkyl substituted with a fluoro radical, and difluoroalkyl is alkyl substituted with two fluoro radicals. It should be recognized that if there are more than one substitutions on a substituent, each non-hydrogen radical may be identical or different (unless otherwise stated).

25 [754] If a substituent is described as being “optionally substituted”, the substituent may be either (1) substituted, or (2) not substituted.

[755] This specification uses the terms “substituent” and “radical” interchangeably.

[756] The prefix “halo” indicates that the substituent to which the prefix is attached is substituted with one or more independently selected halogen radicals. It should be 10 recognized that if a substituent is substituted by more than one halogen radical, those halogen radicals may be identical or different (unless stated otherwise).

[757] The prefix “perhalo” indicates that every hydrogen radical on the substituent to which the prefix is attached is replaced with independently selected halogen radicals, *i.e.*, each hydrogen radical on the substituent is replaced with a halogen radical. 15 If all the halogen radicals are identical, the prefix typically will identify the halogen radical. Thus, for example, the term “perfluoro” means that every hydrogen radical on the substituent to which the prefix is attached is substituted with a fluorine radical. To illustrate, the term “perfluoroalkyl” means an alkyl wherein a fluorine radical is in the place of each hydrogen radical. - 5 Here, one or more hydrogen bound to a carbon in any such substituent may, for example, optionally be replaced with halogen. In addition, the cycloalkyl, aryl, and heteroaryl are typically single-ring substituents containing 3 to 6 ring atoms, and more typically 5 or 6 ring atoms.

[788] A prefix attached to a multi-component substituent only applies to the first
 10 component. To illustrate, the term “alkylcycloalkyl” contains two components: alkyl and cycloalkyl. Thus, the C₁-C₆- prefix on C₁-C₆-alkylcycloalkyl means that the alkyl component of the alkylcycloalkyl contains from 1 to 6 carbon atoms; the C₁-C₆- prefix does not describe the cycloalkyl component. To illustrate further, the prefix “halo” on haloalkoxyalkyl indicates that *only* the alkoxy component of the alkoxyalkyl substituent is
 15 substituted with one or more halogen radicals. If halogen substitution may *alternatively or additionally* occur on the alkyl component, the substituent would instead be described as “halogen-substituted alkoxyalkyl” rather than “haloalkoxyalkyl.” And finally, if the halogen substitution may *only* occur on the alkyl component, the substituent would instead be described as “alkoxyhaloalkyl.”

20 [789] If substituents are described as being “independently selected” from a group, each substituent is selected independent of the other. Each substituent therefore may be identical to or different from the other substituent(s).

[790] When words are used to describe a substituent, the rightmost-described component of the substituent is the component that has the free valence. To illustrate,
 25 benzene substituted with methoxyethyl has the following structure:

As can be seen, the ethyl is bound to the benzene, and the methoxy is the component of the substituent that is the component furthest from the benzene. As further illustration, benzene substituted with cyclohexanylthiobutoxy has the following structure:

[791] When words are used to describe a linking element between two other elements of a depicted chemical structure, the rightmost-described component of the substituent is the component that is bound to the left element in the depicted structure. To illustrate, if the chemical structure is X-L-Y and L is described as methylcyclohexanylethyl, then the chemical would be X-ethyl-cyclohexanyl-methyl-Y.

[792] When a chemical formula is used to describe a substituent, the dash on the left side of the formula indicates the portion of the substituent that has the free valence. To illustrate, benzene substituted with -C(O)-OH has the following structure:

10

[793] When a chemical formula is used to describe a linking element between two other elements of a depicted chemical structure, the leftmost dash of the substituent indicates the portion of the substituent that is bound to the left element in the depicted structure. The rightmost dash, on the other hand, indicates the portion of the substituent that is bound to the right element in the depicted structure. To illustrate, if the depicted chemical structure is X-L-Y and L is described as -C(O)-N(H)-, then the chemical would be:

[794] The term "pharmaceutically acceptable" is used adjectivally in this patent to mean that the modified noun is appropriate for use as a pharmaceutical product or as a part of a pharmaceutical product.

[795] With reference to the use of the words "comprise" or "comprises" or "comprising" in this patent (including the claims), Applicants note that unless the context requires otherwise, those words are used on the basis and clear understanding that they are

to be interpreted inclusively, rather than exclusively, and that Applicants intend each of those words to be so interpreted in construing this patent, including the claims below.

EXAMPLES

[797] The following examples are merely illustrative, and not limiting to the remainder of this disclosure in any way.

20

[798] **Example 1. Preparation of 4-[[4-(3-aminopropoxy)-phenyl]sulfonyl]tetrahydro-2H-pyran-4-carboxylic acid 1,1-dimethylethyl ester, monohydrochloride.**

25 [799] **Part A.** To a solution of t-butylchloroacetate (67 g, 0.44 mol) and 4-fluorothiophenol (50 g, 0.40 mol) in N,N-dimethylformamide (1 L) was added potassium carbonate (62 g, 0.45 mol), followed by dimethylaminopyridine (2 g, 0.02 mol). The mixture was stirred at ambient temperature overnight under nitrogen. Once HPLC showed that the reaction was complete, the mixture was poured into stirring 10% aqueous HCl (1

L) and extracted with ethyl acetate (4x). The combined organic layers were washed with water (2x), dried over magnesium sulfate, filtered, and concentrated *in vacuo* to afford 112 g (100% crude yield) of a brown oil. ^1H NMR confirmed the desired sulfide with no disulfide formation. This material was used without further purification.

5 [800] **Part B.** To a solution of the product from **Part A** (approximately 108g, 0.45 mol) in tetrahydrofuran (400 ml) was added water (700 ml), followed by OxoneTM (600 g, 0.98 mol). The reaction mixture was stirred overnight. Once HPLC showed completion, the reaction mixture was filtered to remove excess OxoneTM, and the mother liquor was then extracted with ethyl acetate (3x). The combined organic layers were
10 washed with water (2x), dried over magnesium sulfate, filtered, and concentrated *in vacuo* to afford 78.3 g (64% crude yield) of a yellow oil. Both ^{19}F and ^1H NMR were consistent with the desired sulfone with no starting material remaining. This material was used without further purification.

 [801] **Part C.** To a solution of the product from **Part B** (78 g, 0.28 mol) in N,N-dimethylacetamide (300 ml) was added potassium carbonate (86 g, 0.62 mol). After
15 stirring for 5 min, 2,2'- (dibromoethyl) ether (79 g, 0.34 mol) was added, followed by 4-dimethylaminopyridine (1.7 g, 0.014 mol) and tetrabutylammonium bromide (4.5 g, 0.14 mol). The reaction mixture was stirred overnight via a mechanical stirrer. Once HPLC showed completion, the reaction mixture was slowly dumped into stirring 10% aqueous
20 HCl (1 L). The resulting yellow solid was collected and washed with hexanes to afford 84 g (86%) of a yellow solid. ^1H NMR confirmed the desired product.

 [802] **Part D.** To a solution of the product from **Part C** (19.8 g, 57.5 mmol) and t-butyl-N-(3-hydroxypropyl) carbamate (11.1 g, 63.3 mmol) in anhydrous N,N-dimethylformamide (300 mL) at 0°C was added sodium hydride (2.8 g, 69.0 mmol; 60%
25 dispersion in mineral oil). After 18 hr, the reaction was quenched with water and concentrated *in vacuo*. The oily residue was partitioned between ethyl acetate and saturated sodium bicarbonate solution. The layers were separated, and the organic layer was washed with brine (3X), dried over sodium sulfate, filtered, and concentrated *in vacuo*. The oily residue was taken up in acetonitrile and again concentrated *in vacuo*. The
30 resulting solid was triturated with diethyl ether, and 15.3 g (53%) of the pure desired product was collected as a white powder. ESMS $m/z = 522$ $[\text{M}+\text{Na}]^+$. The filtrate

contained 11.6 g of material which was shown by HPLC to be 55% product. This material could be purified by flash chromatography to obtain more material if desired.

[803] **Part E.** The product from **Part D** (15.3 g, 30.6 mmol) was taken up in 4N HCl in dioxane (17 mL). After 1 hr, HPLC indicated incomplete reaction, so additional
 5 4N HCl in dioxane (2 mL) was added. After 20 min, the reaction mixture was slowly added to rapidly stirring diethyl ether (400 mL). The resulting oily solid was rinsed with more diethyl ether then dissolved in acetonitrile and concentrated *in vacuo*. 12.3 g (92%) of the desired hydrochloride salt was obtained as a white solid. ESMS $m/z = 400$ $[M+H]^+$.

[805] **Example 7. Preparation of tetrahydro-4-[[4-[[5-(methoxy-methylamino)-5-oxopentyl]oxy] phenyl]sulfonyl]-N-(tetrahydro-2H-pyran-2-yl)oxy]-2H-pyran-4-carboxamide**

5

[806] **Part A.** To a solution of 5-benzyloxy-1-pentanol (32.6 g, 168 mmol) in anhydrous N,N-dimethylformamide (150 mL) at 0°C was added sodium hydride (7.7 g, 192 mmol, 60% dispersion in mineral oil). After 15 min, the reaction mixture was allowed to warm to 20°C, and then re-cooled to 0°C. A solution of 4-[(4-fluorophenyl)sulfonyl]tetrahydro-2H-pyran-4-carboxylic acid, 1,1-dimethylethyl ester (55.1 g, 160 mmol, as prepared in **Example 1, Part C**) in anhydrous N, N-dimethylformamide (100 mL) was added, and the cooling bath removed. After 4 hr, the reaction was concentrated *in vacuo*. The oily residue was partitioned between ethyl acetate and saturated sodium bicarbonate solution. The layers were separated, and the aqueous layer was back extracted with ethyl acetate (2X). The combined extracts were washed with 5% potassium hydrogensulfate, water, and brine (3X); dried over magnesium sulfate; filtered; and concentrated *in vacuo*. The resulting opaque oil solidified upon standing, and was subsequently purified by column chromatography using 10-20% ethyl acetate/ hexanes to afford 67.6 g (81%) of the desired product as a white solid. ESMS m/z = 541 [M+Na]⁺.

20

[807] **Part B.** The product from **Part A** (20.0 g, 38.6 mmol) was dissolved in tetrahydrofuran (80 mL) in a small Fisher/Porter bottle. After purging with a stream of

nitrogen for 5 min, the reaction was charged with 5% palladium on carbon catalyst (4.0 g, Degussa E101 NO/W, 50% water) and pressurized to roughly ~80 psi with hydrogen.

After 1.5 hr, hydrogen uptake had ceased and HPLC analysis indicated the reaction was complete. The reaction was filtered through a bed of celite and the filtrate was

5 concentrated to yield 17.2 g (100%) of the desired alcohol as a viscous oil. This material was used without further purification.

[808] **Part C.** The product from **Part B** (16.5 g, 38.6 mmol) was dissolved in acetonitrile (80 mL). The reaction mixture was treated with carbon tetrachloride (80 mL), water (120 mL), then sodium periodate (24.7 g, 115.7 mmol), and finally ruthenium
10 trichloride (180 mg, 0.9 mmol). After 1 hr, HPLC analysis indicated that the reaction was complete. The reaction mixture was diluted with methylene chloride (300 mL), and the solids were removed by gravity filtration. The layers were separated, and the aqueous layer was extracted with methylene chloride (3X). The combined organic extracts were dried over magnesium sulfate, filtered, and concentrated *in vacuo* to yield a blue solid.
15 This was redissolved in tetrahydrofuran, slurried with activated carbon, filtered, and concentrated *in vacuo* to yield 17.1 g (100%) of an off-white solid. ¹HNMR was consistent with the desired product. This material was used without further purification.

[809] **Part D.** To a solution of the product from **Part C** (17.1 g, 38.6 mmol) in N,N-dimethylformamide (160 ml) was added 1-hydroxybenzotriazole (7.8g, 57.9 mmol),
20 and then 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (10.3 g, 54.0 mmol). After 1.5 hr, N,O-dimethylhydroxylamine HCl (11.3 g, 115.7 mmol) and triethylamine (32.2 ml, 231.4 mmol) were added. The reaction mixture was left stirring at ambient temperature overnight. The mixture was concentrated, and the residue partitioned between ethyl acetate and saturated sodium bicarbonate solution. The aqueous layer was
25 back extracted with ethyl acetate (2X), and the combined organic layers were washed with 5% potassium hydrogensulfate solution, water, and brine (3X), then dried over magnesium sulfate, filtered, and concentrated *in vacuo*. The crude solid was purified by column chromatography using 50% ethyl acetate/hexanes, and 14.7 g (79%) of the desired weinreb amide was obtained as an off-white solid. ESMS $m/z = 508 [M+Na]^+$.

30 [810] **Part E.** The product from **Part D** (6.24 g, 12.85 mmol) was taken up in neat trifluoroacetic acid (50 mL). After 1.5 hr, the trifluoroacetic acid was removed *in vacuo* at 50°C to give the free acid as a syrupy oil. ESMS $m/z = 430 [M+H]^+$. To a

solution of this material in anhydrous N,N-dimethylformamide (25 mL) was added 1-hydroxybenzotriazole (2.14 g, 15.88 mmol), tetrahydropyranhydroxylamine (4.64 g, 39.72 mmol), and triethylamine (5.5 mL, 39.72 mmol), followed by 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (3.35 g, 15.83 mmol). The reaction mixture was heated at 40°C for 3.5 hr, and then cooled to ambient temperature and stirred overnight. The reaction mixture was concentrated *in vacuo* at 60°C. The residue was taken up in ethyl acetate, washed with saturated sodium bicarbonate solution (2X) and brine (3X), dried over sodium sulfate, filtered, and concentrated *in vacuo* to give 8 g of a syrup. The crude material was purified by flash chromatography using 50-100% ethyl acetate/hexanes to give the title compound as a white solid. ESMS $m/z = 529 [M+H]^+$. HRMS calculated for $C_{24}H_{36}N_2O_9S$: 529.2220 $[M+H]^+$, found: 529.2210.

[1049] **Examples 55-89. *In Vitro* MMP Inhibition Analysis**

- [1050] Several hydroxamates and salts thereof were analyzed in *in vitro* assays to
15 determine their ability to inhibit the MMP cleavage of peptide substrates. Inhibition (K_i) and IC₅₀ constants were calculated from the assayed hydroxamate-MMP interactions.

- [1051] Human recombinant MMP-1, MMP-2, MMP-9, MMP-13, and MMP-14 were used in this assay. All enzymes were prepared in Assignee's laboratories following usual laboratory procedures. Protocols for the preparation and use of these enzymes are
20 available in the scientific literature. See, e.g., *Enzyme Nomenclature* (Academic Press, San Diego, CA, 1992) (and the citations therein). See also, Frije et al., *J Biol. Chem.*, 26(24), 16766-73 (1994).

- [1052] The MMP-1 proenzyme was purified from the spent media of MMP-1-transfected HT-1080 cells provided by Dr. Harold Welgus of Washington University (St.
25 Louis, MO). The protein was purified on a zinc chelating column.

[1053] The MMP-2 proenzyme was purified by gelatin Sepharose chromatography from MMP-2-transfected p2AHT2 cells provided by Dr. Gregory Goldberg of Washington University (St. Louis, MO).

[1054] The MMP-9 proenzyme was purified by gelatin Sepharose chromatography from spent media of MMP-9- transfected HT1080 cells provided by Dr. Howard Welgus of Washington University (St. Louis, MO).

[1055] The MMP-13 was obtained as a proenzyme from a full-length cDNA clone
5 using baculovirus, as described by V.A. Luckow, "Insect Cell Expression Technology,"
Protein Engineering: Principles and Practice, pp. 183-218 (edited by J.L. Cleland et al.,
Wiley-Liss, Inc., 1996). The expressed proenzyme was first purified over a heparin
agarose column, and then over a chelating zinc chloride column. The proenzyme was then
10 activated by APMA for use in the assay. Further details on baculovirus expression
systems may be found in, for example, Luckow et al., *J. Virol.*, 67, 4566-79 (1993). *See*
also, O'Reilly et al, *Baculovirus Expression Vectors: A Laboratory Manual* (W.H.
Freeman and Co., New York, NY, 1992). *See also*, King et al., *The Baculovirus*
Expression System: A Laboratory Guide (Chapman & Hall, London, England, 1992).

[1056] The MMP-14 full length cDNA was provided by Dr. Gregory Goldberg of
15 Washington University (St. Louis, MO). The catalytic domain enzyme was expressed in
E. coli inclusion bodies, solubilized in urea, purified on a preparative C-14 reverse phase
HPLC column, and then refolded in the presence of zinc acetate and purified for use.

[1057] All MMPs were activated using 4-aminophenylmercuric acetate ("APMA",
Sigma Chemical, St. Louis, MO) or trypsin. MMP-9 also was activated using human
20 recombinant MMP-3 (purified in Assignee's laboratory following standard cloning and
purification techniques).

[1058] Two fluorogenic, methoxycoumarin-containing polypeptide substrates were
used in the MMP inhibition assays:

25 (I)

(II)

Here, "Dpa" is 3-(2,4-dinitrophenyl)-L-2,3-diaminopropionyl group, and "MCA" is 7-
methoxycoumarin-4-yl acetyl. Substrate (I) was purchased from Baychem (Redwood
30 City, CA), and substrate II was prepared Assignee's laboratory. Substrate I was used in
the IC₅₀ determination assays, while substrate II was used in the K_i determination assays.
In the absence of MMP inhibitory activity, either substrate is cleaved at the Gly-Leu

peptide bond. This cleavage separates the highly fluorogenic peptide from the 2,4-dinitrophenyl quencher, thus resulting in increase of fluorescent intensity.

[1059] The stock solutions of the assayed hydroxamates (or salts thereof) were prepared in 1% dimethyl sulfoxide (DMSO). These stock solutions were diluted in Buffer A (100 mM Tris-HCl, 100 mM NaCl, 10 mM CaCl₂, 0.05% polyoxyethylene 23 lauryl ether, pH 7.5) to obtain solutions with different hydroxamate concentrations, *i.e.*, assay solutions with different concentrations of the assayed MMP inhibitory compound. The experiment controls contained the same amount of Buffer A/DMSO as the assayed sample, but contained no hydroxamate (or salt thereof).

[1060] The assays from which the IC₅₀ determinations were made were performed as follows. The MMPs were activated with either trypsin or APMA (4-aminophenylmercuric acetate, Sigma Chemical, St. Louis, MO). The assayed hydroxamate samples were incubated in MicrofluorTM White Plates (Dynatech, Chantilly, VA) and analyzed on a Perkin Elmer L550 plate reader (Norwalk, CT). The excitation wavelength was 328 nm, and the emission wavelength – 415 nm. All samples (assayed hydroxamates and controls) were incubated in separate plates at room temperature in the presence of 4 μM of MMP substrate (I). As stated in the previous paragraph, samples containing varying concentrations of the same assayed hydroxamate were prepared. Inhibition was measured as a reduction in fluorescent intensity as a function of MMP inhibitor concentration.

[1061] The assays from which the K_i determinations were made were performed as follows. The assayed hydroxamate samples were incubated in separate wells of untreated white polystyrene plates (Nunc Nalgene International, Rochester, NY), and analyzed on a Tecan SpectraFlour Plus plate reader. The excitation wavelength was 330 nm, and the emission wavelength – 420 nm. All samples (assayed hydroxamates and controls) were incubated in separate plate wells at room temperature for 1 hr in the presence of 4 μM of MMP substrate (II). In the absence of MMP inhibitory activity, substrate II was cleaved at the Gly-Leu bond resulting in an increase of relative fluorescence. Inhibition was observed as a reduced rate of this increase in relative fluorescence. The various hydroxamates were analyzed using a single low enzyme concentration with a single substrate concentration fixed at or below the K_m. This protocol is a modification of method by Knight et al., *FEBS Lett.*, 296(3), 263-266 (1992). Apparent inhibitory

constants were determined by non-linear regression of reaction velocity as a function of inhibitor and enzyme concentration using Morrison's equation, as described by Kuzmic, Anal. Biochem. 286, 45-50 (2000). Modifications were made in the non-linear regression method to allow a common control reaction rate and effective enzyme concentration to be shared between all dose-response relationships on a given assay plate. Since the substrate concentration was chosen to be at or below the K_m , the apparent K_i 's from this analysis were reported as K_i 's without correction for the influence of substrate.

[1062] The above protocols were used to determine IC₅₀ constants and K_i values values for several of the compounds in Examples 1-52 above. The results are shown in Table 5. All values in Table 5 are given in nM units. The K_i measurements are in parenthesis.

[1063] Example 90. *In Vivo* Angiogenesis Assay

[1064] The study of angiogenesis depends on a reliable and reproducible model for the stimulation and inhibition of a neovascular response. The corneal micropocket assay provides such a model of angiogenesis in the cornea of a mouse. See, *A Model of Angiogenesis in the Mouse Cornea*; Kenyon, BM, et al., *Investigative Ophthalmology & Visual Science*, July 1996, Vol. 37, No. 8.

[1065] In this assay, uniformly sized Hydron™ pellets containing bFGF and sucralfate are prepared and surgically implanted into the stroma mouse cornea adjacent to the temporal limbus. The pellets are formed by making a suspension of 20 µL sterile saline containing 10 µg recombinant bFGF, 10 mg of sucralfate and 10 µL of 12 percent Hydron™ in ethanol. The slurry is then deposited on a 10 x 10 mm piece of sterile nylon mesh. After drying, the nylon fibers of the mesh are separated to release the pellets.

[1066] The corneal pocket is made by anesthetizing a 7 week old C57Bl/6 female mouse, then proptosing the eye with a jeweler's forceps. Using a dissecting microscope, a central, intrastromal linear keratotomy of approximately 0.6 mm in length is performed with a #15 surgical blade, parallel to the insertion of the lateral rectus muscle. Using a
5 modified cataract knife, a lamellar micropocket is dissected toward the temporal limbus. The pocket is extended to within 1.0 mm of the temporal limbus. A single pellet is placed on the corneal surface at the base of the pocket with a jeweler's forceps. The pellet is then advanced to the temporal end of the pocket. Antibiotic ointment is then applied to the eye.

[1067] Mice are dosed on a daily basis for the duration of the assay. Dosing of the
10 animals is based on bioavailability and overall potency of the compound. An exemplary dose is 10 or 50 mg/kg (mpk) bid, po. Neovascularization of the corneal stroma is permitted to continue under the influence of the assayed compound for 2 days. At that point, the degree of angiogenic inhibition is scored by viewing the neovascular progression with a slit lamp microscope.

[1068] The mice are anesthetized and the studied eye is once again proptosed. The
15 maximum vessel length of neovascularization, extending from the limbal vascular plexus toward the pellet is measured. In addition, the contiguous circumferential zone of neovascularization is measured as clock hours, where 30 degrees of arc equals one clock hour. The area of angiogenesis is calculated as follows.

20

$$\text{area} = \frac{(0.4 \times \text{clock hours} \times 3.14 \times \text{vessel length (in mm)})}{2}$$

[1069] Five to six mice should be utilized for each compound in each study. The
25 studied mice are thereafter compared to control mice and the difference in the area of neovascularization is recorded as an averaged value. Each group of mice so studied constitutes an "n" value of one, so that "n" values greater than one represent multiple studies whose averaged result is provided in the table. A contemplated compound typically exhibits about 25 to about 75 percent inhibition, whereas the vehicle control
30 exhibits zero percent inhibition.

[1070] **Example 91. Tumor Necrosis Factor Assays**

[1071] Cell Culture.

[1072] The cells used in the assay are the human monocytic line U-937 (ATCC CRL-1593). The cells are grown in RPMI w/10% FCS and PSG supplement (R-10) and are not permitted to overgrow. The assay is carried out as follows:

5 [1073] 1. Count, then harvest cells by centrifugation. Resuspend the pellet in R-10 supplement to a concentration of 1.540×10^6 cells/mL.

[1074] 2. Add test compound in 65 μ L R-10 to the appropriate wells of a 96-well flat bottom tissue culture plate. The initial dilution from a DMSO stock (100 mM compound) provides a 400 μ M solution, from which five additional three-fold serial dilutions are made. Each dilution of 65 μ L (in triplicate) yields final compound test
10 concentrations of 100 μ M, 33.3 μ M, 11.1 μ M, 3.7 μ M, 1.2 μ M and 0.4 μ M.

[1075] 3. The counted, washed and resuspended cells (200,000 cells/well) in 130 μ L are added to the wells.

[1076] 4. Incubation is for 45 min to 1 hr at 37°C in 5% CO₂ in a water saturated container.

15 [1077] 5. R-10 (65 μ L) containing 160 ng/mL PMA (Sigma) is added to each well.

[1078] 6. The test system is incubated at 37°C in 5% CO₂ overnight (18-20 hr) under 100% humidity.

[1079] 7. Supernatant, 150 μ L, is carefully removed from each well for use in the ELISA assay.

20 [1080] 8. For toxicity, a 50 μ L aliquot of working solution containing 5 mL R-10, 5 mL MTS solution [CellTiter 96 Aqueous One Solution Cell Proliferation Assay Cat.#G358/0,1 (Promega Biotech)] and 250 μ L PMS solution are added to each well containing the remaining supernatant and cells and the cells incubated at 37°C in 5% CO₂ until the color develops. The system is excited at 570 nm and read at 630 nm.

[1109] **Example 92. *In Vitro* Aggrecanase Inhibition Analysis**

[1110] Assays for measuring the potency (IC₅₀) of a compound toward inhibiting aggrecanase are known in the art.

25 [1111] One such assay, for example, is reported in European Patent Application Publ. No. EP 1 081 137 A1. In that assay, primary porcine chondrocytes from articular joint cartilage are isolated by sequential trypsin and collagenase digestion followed by collagenase digestion overnight and are plated at 2×10^5 cells per well into 48 well plates with 5 µCi/ml ³⁵S (1000 Ci/mmol) sulphur in type 1 collagen coated plates. Cells are
30 allowed to incorporate label into their proteoglycan matrix (approximately 1 week) at 37°C under an atmosphere of 5% CO₂. The night before initiating the assay, chondrocyte monolayers are washed 2 times in DMEM/1% PSF/G and then allowed to incubate in

fresh DMEM/1% FBS overnight. The next morning, chondrocytes are washed once in DMEM/1% PSF/G. The final wash is allowed to sit on the plates in the incubator while making dilutions. Media and dilutions are made as described in the following Table 6:

Table 6

control media	DMEM alone
IL-1 media	DMEM + IL-1 (5ng/ml)
drug dilutions	<p>Make all compound stocks at 10 mM in DMSO.</p> <p>Make a 100 μM stock of each compound in DMEM in 96-well plate. Store in freezer overnight.</p> <p>The next day, perform serial dilutions in DMEM with IL-1 to 5 μM, 500 nM, and 50 nM.</p> <p>Aspirate final wash from wells and add 50 μM of compound from above dilutions to 450 μL of IL-1 media in appropriate wells of the 48 well plates.</p> <p>Final compound concentrations equal 500 nM, 50 nM, and 5 nM.</p> <p>All samples completed in triplicate with control and IL-1 alone on each plate.</p>

5

Plates are labeled and only the interior 24 wells of the plate are used. On one of the plates, several columns are designated as IL-1 (no drug) and control (no IL-1, no drug). These control columns are periodically counted to monitor ³⁵S-proteoglycan release. Control and IL-1 media are added to wells (450 μ L) followed by compound (50 μ L) so as to initiate the assay. Plates are incubated at 37°C with 5% CO₂ atmosphere. At 40-50% release (when CPM from IL-1 media is 4-5 times control media) as assessed by liquid scintillation counting (LSC) of media samples, the assay is terminated (about 9 to about 12 hours). Media is removed from all wells and placed into scintillation tubes. Scintillate is added and radioactive counts are acquired (LSC). To solubilize cell layers, 500 μ L of papain digestion buffer (0.2 M Tris, pH 7.0, 5 mM DTT, and 1 mg/ml papain) is added to each well. Plates with digestion solution are incubated at 60°C overnight. The cell layer is removed from the plates the next day and placed in scintillation tubes. Scintillate is then added, and samples counted (LSC). The percent of released counts from the total present in each well is determined. Averages of the triplicates are made with control background

10

15

subtracted from each well. The percent of compound inhibition is based on IL-1 samples as 0% inhibition (100% of total counts).

[1112] Another assay for measuring aggrecanase inhibition is reported in WIPO Int'l Publ. No. WO 00/59874. That assay reportedly uses active aggrecanase accumulated
5 in media from stimulated bovine cartilage (BNC) or related cartilage sources and purified cartilage aggrecan monomer or a fragment thereof as a substrate. Aggrecanase is generated by stimulation of cartilage slices with interleukin-1 (IL-1), tumor necrosis factor alpha (TNF- α), or other stimuli. To accumulate BNC aggrecanase in culture media, cartilage reportedly is first depleted of endogenous aggrecan by stimulation with 500
10 ng/ml human recombinant IL- β for 6 days with media changes every 2 days. Cartilage is then stimulated for an additional 8 days without media change to allow accumulation of soluble, active aggrecanase in the culture media. To decrease the amounts of matrix metalloproteinases released into the media during aggrecanase accumulation, agents which inhibit MMP-1, -2, -3, and -9 biosynthesis are included during stimulation. This BNC
15 conditioned media containing aggrecanase activity is then used as the source of aggrecanase for the assay. Aggrecanase enzymatic activity is detected by monitoring production of aggrecan fragments produced exclusively by cleavage at the Glu373-Ala374 bond within the aggrecan core protein by Western analysis using the monoclonal antibody, BC-3 (Hughes, et al., *Biochem J*, 306:799-804 (1995)). This antibody reportedly
20 recognizes aggrecan fragments with the N-terminus, 374ARGSVIL, generated upon cleavage by aggrecanase. The BC-3 antibody reportedly recognizes this neopeptide only when it is at the N-terminus and not when it is present internally within aggrecan fragments or within the aggrecan protein core. Only products produced upon cleavage by aggrecanase reportedly are detected. Kinetic studies using this assay reportedly yield a K_m
25 of $1.5 \pm 0.35 \mu M$ for aggrecanase. To evaluate inhibition of aggrecanase, compounds are prepared as 10 mM stocks in DMSO, water, or other solvents and diluted to appropriate concentrations in water. Drug (50 μL) is added to 50 μL of aggrecanase-containing media and 50 μL of 2 mg/ml aggrecan substrate and brought to a final volume of 200 μL in 0.2 M Tris, pH 7.6, containing 0.4 M NaCl and 40 mM $CaCl_2$. The assay is run for 4 hr at
30 37°C, quenched with 20 mM EDTA, and analyzed for aggrecanase-generated products. A sample containing enzyme and substrate without drug is included as a positive control and enzyme incubated in the absence of substrate serves as a measure of background.

Removal of the glycosaminoglycan side chains from aggrecan reportedly is necessary for the BC-3 antibody to recognize the ARGSVIL epitope on the core protein. Therefore, for analysis of aggrecan fragments generated by cleavage at the Glu373-Ala374 site, proteoglycans and proteoglycan fragments are enzymatically deglycosylated with

5 chondroitinase ABC (0.1 units/10 μ g GAG) for 2 hr at 37°C and then with keratanase (0.1 units/10 μ g GAG) and keratanase II (0.002 units/10 μ g GAG) for 2 hr at 37°C in buffer containing 50 mM sodium acetate, 0.1 M Tris/HCl, pH 6.5. After digestion, aggrecan in the samples is precipitated with 5 volumes of acetone and resuspended in 30 μ L of Tris glycine SDS sample buffer (Novex) containing 2.5% beta mercaptoethanol. Samples are

10 loaded and then separated by SDS-PAGE under reducing conditions with 4-12% gradient gels, transferred to nitrocellulose and immunolocalized with 1:500 dilution of antibody BC3. Subsequently, membranes are incubated with a 1:5000 dilution of goat anti-mouse IgG alkaline phosphatase second antibody and aggrecan catabolites visualized by incubation with appropriate substrate for 10-30 minutes to achieve optimal color development. Blots

15 are quantitated by scanning densitometry and inhibition of aggrecanase determined by comparing the amount of product produced in the presence versus absence of compound.
